We will present a recent experiment for elastic scattering of  ${}^7\text{Be} + {}^{90}\text{Zr}$  at five sub – and near-barrier energies, namely at 21.5, 22.5, 24, 27 and 28 MeV, for determining the optical potential. The experiment was performed at the *TriSol* radioactive beam facility of Notre Dame University, simultaneously with elastic scattering and breakup measurements of  ${}^8\text{B} + {}^{90}\text{Zr}$ , the last performed at 28MeV. This optical potential will be used as one of the coupling potentials in our CDCC calculations for  ${}^8\text{B}$ . Further on we will look for the resemblance of this potential either with the one exhibited by  ${}^7\text{Li}$  or the one by  ${}^6\text{Li}$ , extracting useful conclusions for their structure [1-3]. Preliminary data will be presented and discussed.
